

Pediatric Mandibular Distractor

with anti-reverse mechanism

Pediatric Mandibular Distractor

Milled device

The distraction body is a single unit milled from a solid block of titanium, designed to diminish weak-points between the body and footplate connection.

Anti-reverse mechanism

This mechanism is located within the distractor body. Once activated it is designed to prevent the device from distracting in the reverse direction.

Type II anodization

May reduce the risk of tissue and bone adhesion, to assist in simplifying the device removal.

Internal distraction mechanism

With less exposure to the osteotomy site, risk of bone and tissue interference may be reduced.
